28 JULY 2004

PRESENTATION BY PACIFIC ECONOMICS GROUP

[8.05 am]

CHAIR: Good morning everyone. I'd like to welcome you to the fourth and final day of the Commission's conference on the Gas Pipelines Inquiry Draft report. We must have worked far too hard yesterday because Wanganui Gas -- oh no, there they are, they have been faithful throughout the whole thing, so I'm glad to see you're back this morning. I would like, though, to thank everyone once again for assisting us yesterday to get through the material.

This morning we are starting with a session with Pacific Economics Group and I believe we have Dr Kaufmann on the video screen. PEG is presenting on behalf of NGC and Vector I believe. So with that brief comment we'll ask for introductions for the sake of the record and also say welcome to you, Dr Kaufmann, a familiar face, even if it is on the video screen rather than in the room, so please proceed when you're ready.

MR SHEPHERD: Good morning Commissioners, I'm just here really to introduce Larry given that he's on video. As you mentioned his work, a benchmarking study and comments on the Meyrick report were sponsored by Vector and NGC and I'll hand over to Larry to take the session forward.

CHAIR: Just before we start I notice there are as many slides as there are pages in the original report and we've got a fair amount of time, but I want to ensure that a significant amount of time is left at the end for questions, Dr Kaufmann, so I'm going to ask you to move through the slides as quickly as you can, covering the

1 points that need to be covered. So I think we have until
2 10.15 and I think we should ensure we have at least 45
3 minutes for questions, thanks. Please begin when you're
4 ready.

5 **DR KAUFMANN:** Okay, thank you. I will move quickly, can
6 everyone hear me okay?

7 **CHAIR:** Yes, we can, thank you.

8 **DR KAUFMANN:** Okay, great. Well thanks for giving me the
9 opportunity to present. I had hoped that my presentation
10 on PowerPoint would be beamed across, it would also be
11 available, but I guess the technology isn't going to allow
12 that, but you can follow along in the handout. Today I'm
13 going to talk about two things, one is my analysis of the
14 reports that were done by Meyrick & Associates, as you
15 know there were two reports, the Meyrick report was the
16 comparative benchmarking report, and secondly I'm going to
17 talk about some benchmarking evidence that I developed on
18 behalf of Vector and NGC.

19 My overall conclusion really is that ultimately the
20 Meyrick & Associates benchmarking results were really
21 limited by the lack of available data. Dr Lawrence said
22 that he made the best use of available data, I believe he
23 said that in the report and I don't necessarily disagree
24 with that, but there really was a very limited data set
25 available and used for the benchmarking studies that have
26 been used in the inquiry, only a cross-section of 14
27 companies for one year and it's very difficult to make
28 reliable inferences on efficiency using such a small
29 sample.

30 I think one of the implications of having such a small
31 data set was that Dr Lawrence was essentially required to

1 use less powerful benchmarking techniques and because of
2 that the benchmarking techniques that were used didn't
3 really control adequately for a number of factors that are
4 particularly important in New Zealand, and I'll be talking
5 about some of those factors very shortly.

6 For this study I was approached by the gas
7 distributors to do an alternative study relying on our
8 database and Pacific Economics Group has been developing a
9 gas distribution database for US gas distributors for over
10 10 years now and we think it's the best that's available
11 to do really rigorous benchmarking for gas distribution.
12 And we use this database and applied what I believe are
13 much more rich and powerful benchmarking techniques to
14 that data and our conclusion was that NGC and Vector are
15 really pretty good cost performers. The data suggests
16 that they're significantly superior, relative to what's
17 expected, given the 40 companies in our database, and that
18 differs quite a bit from the Meyrick results. Vector and
19 NGC were generally well below the benchmarks constructed
20 for the other companies in the sample and in some models
21 were in fact 13th and 14th of the 14 companies.

22 So I'm going to talk about that, and before I do I'm
23 just going to say a few words about the Meyrick results,
24 beginning with the productivity growth study. I'm on
25 slide 4 right now. That was a fairly short report and
26 that study was limited by the fact that Meyrick was only
27 able to obtain enough time series data to estimate total
28 factor productivity growth for one of the New Zealand
29 distributors and that was NGC.

30 NGC's customer base really only represents about a
31 quarter of the customers served in the country, in the

1 entire industry and in my opinion that's just not
2 comprehensive enough to be a very reliable estimate of the
3 underlying productivity growth of the entire industry.
4 Three quarters of the industry isn't accounted for and
5 it's really difficult to project from one company's TFP
6 growth to entire industry under the best of circumstances
7 because companies' TFP can be very variable from year
8 to year, for example it can depend on the timing of
9 investment and a number of things, that's less true on an
10 industry level.

11 So I think my message there is simply that I don't
12 have any necessary concerns about the study itself in the
13 estimate that was obtained, but it's difficult to use that
14 number for that company alone as a proxy for the entire
15 industry.

16 Turning then to the benchmarking study that was done,
17 there Meyrick benchmarked the four New Zealand
18 distributors relative to ten Australian gas distributors
19 and the benchmarking technique that was used was a
20 multilateral total factor productivity index level. So
21 it's similar to the TFP study that was done for TFP growth
22 but here the same sort of information is being used to
23 construct levels of productivity relative to a baseline
24 productivity level.

25 Now let me say that the multilateral TFP index is
26 certainly a legitimate technique, I'm not questioning that
27 technique per se, but I think most benchmarking
28 practitioners would agree that it's one of the least
29 powerful techniques, it's certainly not as powerful as
30 econometrics done well. It's more of a blunt tool I think
31 as opposed to a more finely tuned sort of instrument, and

1 when Pacific Economics Group uses multilateral TFP
2 indexes, we very rarely do that as a sole source of
3 benchmarking evidence, we'll do that as a supplementary or
4 complementary source of evidence, but we usually try to
5 rely on what we believe are more reliable sort of
6 techniques to make more valid inferences on efficiency.

7 Some of the concerns I have with the Meyrick approach,
8 there are really three. One is that it doesn't control
9 adequately for differences in the scale of output and the
10 economies of scale that might be realised, it doesn't
11 control well for customer density, differences in customer
12 density and the impact that that can have on cost
13 performance and only a single year's worth of data was
14 used. That's less of a concern than the other two.

15 So first on economies of scale and I'm on slide 6 now.
16 One of the main problems with multilateral TFP indexes is
17 that they don't control as well as econometric methods for
18 economies of scale and this is a very important issue in
19 New Zealand because the gas distributors in the country
20 are so small by international standards and if you don't
21 have a benchmarking technique that controls for the cost
22 disadvantage of being small relative to the minimum
23 efficient scale gas distributors can obtain by expanding
24 output then companies are really going to be unfairly
25 disadvantaged. It's very important to have a technique
26 that gives companies appropriate credit for the scale
27 economies they may or may not have attained.

28 It's fairly straightforward to demonstrate this. I
29 have the map, a very simple demonstration on slide 6 and
30 7. If economies of scale exist and by definition, if
31 you're comparing two companies at a point in time then the

1 changes in cost are going to be different than -- they're
2 not going to be as great as differences in output between
3 two companies.

4 You probably remember the sort of classic U-shaped
5 average cost curve from economic principle classes; and
6 what that is is average cost is cost divided by output and
7 on the vertical axis you've got cost and on the horizontal
8 cost you have output. The shape of the curve is that it
9 starts high so that unit costs are much higher at very low
10 levels of output, they tend to decline as companies expand
11 and then they start to flatten out.

12 That area of the decline, that's the realisation of
13 economies of scale. You can just dry down your unit costs
14 by expanding output, then there's typically a long flat
15 version where the potential to realise additional scale
16 economies is relatively small and then at some point the
17 cost curve can actually turn up meaning companies have
18 exceeded the minimum efficient scale, they're actually too
19 large and there are diseconomies associated with that.

20 So if you're looking at two companies at a point in
21 time, if one company is relatively small then it's going
22 to be way to the left on that curve and it's going to be
23 up at the point where, because its output is small, its
24 unit costs are relatively high. So you can compare two
25 companies at a point in time and that's what I've done
26 here in this math.

27 If scale economies exist then the unit cost for the
28 company that's smaller, and in my example I've got
29 companies A and B, A is the larger company and they both
30 face the same input prices and if there are scale
31 economies then if you just take the total cost of company

1 A divided by the output of company A, if A is bigger than
2 B then that ratio is going to be smaller than the same
3 unit cost ratio for company B. You can just invert that,
4 then what you have is output divided by cost for A is
5 greater than output divided by cost for B.

6 Turning to slide 7, cost just has two components, it's
7 equal to the product of input price and input quantity, so
8 I substitute that for the cost on the denominator of each
9 of those expressions and then divide through by input
10 prices which are the same for the two companies, and what
11 we're left with is that output quantity over input
12 quantity for A is greater than the output quantity over
13 input quantity for B. But this is exactly what the
14 multilateral TFP index is. The multilateral TFP index is
15 a ratio of an number of outputs aggregated together
16 divided by a number of inputs that are also aggregated
17 together.

18 So what this shows is that if you have economies of
19 scale for two companies, one company is larger than
20 another and it's enjoying economies of scale because of
21 that, that's going to be directly reflected in a
22 multilateral TFP index. Other things can be in there as
23 well, there can be real efficiency gains between company A
24 and company B, that can also be reflected in the index,
25 but economies of scale are certainly going to be in there
26 and you need a more powerful sort of technique to untangle
27 the impact of scale economies from other things and to try
28 to isolate what you're really interested in, which is the
29 underlying efficiency of the two enterprises. So I think
30 that's a really important point and it's really one of the
31 real deficiencies of this technique.

1 Turning then to customer density on slide 8, this is a
2 very difficult issue to control for and I know the Meyrick
3 study takes a number of cracks at it, there are three
4 different models and they all -- the two alternate models
5 were primarily designed to control for differences in
6 density among the companies. The model one, which I kind
7 of think of as the base model, has two outputs, and those
8 are number of customers and volumes, and two inputs which
9 are kilometres of distribution main and O&M costs, and in
10 a multilateral TFP index the outputs form the numerator of
11 the index and the inputs form the denominator of the
12 index. You need a way to weight those things together to
13 come up with a comprehensive input and comprehensive
14 output.

15 In the Meyrick study the customer numbers receive an
16 86 percent weight and volumes receive a 14 percent weight
17 in output and those weights actually come from a study
18 that we'd done earlier in Victoria. The Meyrick study
19 doesn't say what the weights are for kilometres and O&M
20 costs, but because gas distributors are capital intensive
21 I think it's likely that more than half of the weight is
22 related to kilometres. I did some back of the envelope
23 calculations with the data that were available in the
24 report and I came up with a weight of approximately 62
25 percent. That's just an estimate.

26 So you have kilometres of line receiving most of the
27 weight on the denominator of that index and customers
28 receiving most of the weight on the numerator of the
29 index, and the ratio of numbers of customers to kilometres
30 of line is in fact a measure of customer density, so what
31 that shows is that you have this business condition that

1 you're trying to control for, customer density; you don't
2 want that to be distorting the efficiency measure that
3 you're computing and in this case there's a direct
4 correlation, a very strong correlation simply between
5 customer density and the multilateral TFP index because of
6 the fact that the components of the customer density
7 measure are so highly correlated with the same sort of
8 components in the numerator and denominator of the
9 multilateral TFP index.

10 Turning to slide 9, model 2 is an attempt to control
11 to some extent for differences in customer density and
12 it's an alternate model where the inputs now are the ODV
13 values of the capital stock and the O&M, so ODV has been
14 substituted for kilometres of line and in the report it
15 said this was justified in part by the fact that if you're
16 just using kilometres of line you're not picking up all
17 the costs associated with networks and that you would
18 expect there to be more costs associated with more dense
19 networks because there are more off-takes, more services,
20 more meters that sort of thing. All those things are
21 going to be -- if you have more customers along a gas
22 distribution main then you're going to have all those
23 extra costs and those would be reflected in the ODV value
24 but they're not reflected in the kilometres of line.

25 So the thinking was evidently to have those costs
26 reflected in the measure and if the costs are reflected
27 then the measure is improved and I do agree that the
28 measure is improved, but in my opinion the issue is
29 actually different than that. The real issue is not just
30 to get the costs associated with more dense networks, but
31 it's really to look at the relationship between cost and

1 customer density and how that relationship varies.

2 So, for example, let's say you have a 10 kilometre gas
3 distribution main from an off-take point single customer
4 at the end of that main, obviously the real issue there
5 is -- that's going to be very expensive to serve that
6 customer because now you have 10 kilometres of gas
7 distribution main taking it from the city gate to that
8 customer's location. But if you have 100 different
9 houses, say, along that line you can spread the cost of
10 that gas distribution main over the bigger customer base
11 and having more customers along that line is a reflection
12 of higher customer density and what that does, yes, there
13 are more costs associated with each of those off-takes and
14 meters and things like that, so there are going to be more
15 costs associated with each of those customers but the unit
16 costs are going to be lower.

17 Customer density is something that -- higher levels of
18 customer density are a favourable condition for
19 distributors and it tends to improve cost performance not
20 diminish it. The model 2 multilateral TFP index isn't
21 subtle enough to really capture that relationship. All
22 it's really doing is taking more costs associated with
23 density, putting them in the denominator and by doing that
24 it tends to collapse the score, the multilateral TFP
25 scores, but it's not really addressing the fundamental
26 issue which is how costs relate to customer density. In
27 fact the report seems to almost say that the customer
28 having more dense networks raises costs when in fact the
29 opposite is true. It does raise costs but it reduces unit
30 costs. That's my concern with model 2.

31 Model 3 begins with model 1, so now again we have

1 customers and volumes as the outputs on the numerator of
2 the index and we're back to kilometres and O&M costs on
3 the denominator of the index. But Dr Lawrence realised
4 that that ratio could be distorted by differences in
5 customer density and there was an attempt made to adjust
6 that measure for differences in both customer and energy
7 density and what was done there is one of the companies in
8 the sample AGL was at approximately average levels, sample
9 average levels for customer density and energy density,
10 and AGLGN essentially became a kind of benchmark within
11 the sample.

12 What Dr Lawrence did was he adjusted the customer
13 numbers and the volumes and kept the kilometres of line
14 the same for each of the companies, but adjusted the
15 numbers of customers and the volumes for each of the other
16 sample companies so that they were equal to the N over Km
17 ratio for AGLGN and the V over N ratio for AGLGN, and he
18 also recognised that in doing that, by adding output
19 essentially to each of the other companies in the sample
20 there would be costs associated with that and to recognise
21 those costs the O&M costs for each of the sample companies
22 were adjusted by 0.86 times the change in customer numbers
23 that were applied to each company and by 0.14 by the
24 change in volumes. Those O&M costs then appear in the
25 denominator of the multilateral TFP index formula. So it
26 was an attempt to make a proxy adjustment so all companies
27 in the sample in a sense were similar, so that they were
28 operating at similar levels of customer density and energy
29 density.

30 Slide 10 now. I have a number of concerns with that.
31 One is that the 0.86 and 0.14 weights in fact come from a

1 study that we did in Victoria about three years ago and
2 those weights do not refer to the relationship between
3 outputs and O&M costs, they refer to the relationship
4 between outputs and total cost. You can derive weights
5 for outputs and O&M costs but it's more complicated. So
6 in fact I understand this is just kind of a rough and
7 ready proxy but the way the weights were used don't really
8 reflect the actual weights that appear in our study.

9 In fact the actual relationship between cost and
10 output is much more complicated than those first order
11 coefficients. I'm going to talk about PEG's cost model
12 and show a little bit of some of that complexity in terms
13 of how we model the relationship between cost and various
14 cost drivers, but one real problem with that again is that
15 it doesn't reflect economies of scale, it's kind of
16 positing this linear relationship between changes in
17 customers and changes in volumes and how that would affect
18 changes in costs.

19 If companies are realising scale economies then that
20 relationship isn't going to be linear. For relatively
21 small companies, if you change customers and you change
22 volumes they're realising scale economies, so their costs
23 are going to rise less rapidly than the changes in those
24 outputs. For other companies that might be close to
25 minimum efficient scale then there might be a linear sort
26 of change. So the relationship is more complicated and
27 it's going to vary from company to company depending on
28 how large they are and the scale economies that they have.

29 I guess a more fundamental sort of point, and I think
30 this was an interesting exercise, and I've never seen it
31 done before and I did think it was interesting, but I

1 almost feel like what's been done here is kind of bringing
2 the mountain to Mohammed instead of bringing Mohammed to
3 the mountain. When you think about it, what benchmarking
4 is designed to do is you're focused on coming up with a
5 technique, or a formula that you can use to evaluate the
6 efficiency of enterprises, but you know that efficiency
7 can vary for a number of factors beyond companies' control
8 and you want to be able to control for those factors, you
9 want your technique to be able to control for that.

10 So the way to do that and the way it's typically done
11 is you develop a technique, then once you have this
12 formula or model developed you would take the conditions
13 of the companies themselves, the specific business
14 conditions they operated under and put those into the
15 model and when you do that you get a benchmarking measure
16 that's tailored to the conditions of the company, it
17 reflects each company's specific conditions.

18 Here almost the opposite was done. AGLGN was the
19 benchmark and what was done was that rather than having
20 the benchmark reflect the company's data, the company's
21 data was adjusted to reflect the benchmark, the benchmark
22 company for the sample. That's really not the same thing
23 because you're not basing -- the measures that are
24 ultimately constructed, the multilateral TFP numbers that
25 are constructed in the end aren't based on the company's
26 own data, they're based on hypothetical data, and again
27 economies of scale can make a difference in terms of the
28 impact that this sort of approach can have on the
29 benchmarks for individual companies, and I actually just
30 noticed this in the report this morning, but Dr Lawrence
31 also noticed that and on page 49 he talked about what the

1 potential impact of that, of not controlling for scale
2 economies in the model 3 multilateral TFP indexes and I'll
3 just read this quote it said:

4 "it should be noted that this approach is likely to be
5 conservative as it does not allow for economies of size.
6 If there are economies of size then operating and
7 maintenance expenditure would change by less than the
8 weighted average of the two output components".

9 I agree with that.

10 "all else equal this would provide an advantage to the
11 smaller distributors".

12 That statement is not true because if in fact cost is
13 going up by less than the cost change that's computed for
14 this proxy, then remember that O&M costs appear in the
15 denominator of this ratio and if you have a smaller number
16 in the denominator then that's going to raise the ratio,
17 that's going to lead to a higher computed multilateral TFP
18 index.

19 So it's true that economies of scale are important and
20 I think it's not true that this is a conservative approach
21 that's going to tend to favour the smaller New Zealand
22 companies, it really is a bias that works against them,
23 and it's an unfair bias.

24 Moving now to slide 11, final concern I had with the
25 Meyrick study is the data themselves and not the quality
26 of the data because I'm sure that, and in fact the report
27 said that the reason a single year's worth of data were
28 chosen was that the data become more reliable over time
29 and they wanted to use the best available which are the
30 most recent data, so that certainly is a legitimate reason
31 for focusing on a single year's worth of data.

1 But there's a problem when you're only using
2 one year's worth of data to construct a benchmark, there
3 can be a number of factors that can affect both outputs
4 and inputs in that single year, and I think that's
5 particularly true for gas distributors. Gas distributors'
6 volumes in particular fluctuate quite a bit from year
7 to year more typically than electric distributors and the
8 fluctuations go in both directions. In particular gas
9 demand is very sensitive to cold weather.

10 I don't know that this is the case but it's a
11 possibility that could be affecting the results in the
12 Meyrick study because the Victorian companies tend to do
13 very well in the multilateral TFP indexes that are
14 computed and it's possible that there was just a very cold
15 winter in Victoria and that raised space heating demand.
16 So there are a lot of volumes associated with that year
17 and that in and of itself is going to raise the TFP index
18 in that year, it's a possibility. Again that is not a
19 real reflection of efficiency that's just obviously a
20 random effect that's affecting the company's output.

21 Another issue is there might be changes in cost
22 allocations in a given year and if you're just basing your
23 benchmark on a single year's worth of data that benchmark
24 is going to be more sensitive to cost allocations, and
25 cost reallocations. Again, anything else that might be
26 excluded from the model that you're not controlling for,
27 the probability that any of those excluded variability is
28 going to be affecting a single year's worth of data, the
29 impact of that excluded variable in that single year is
30 going to be magnified. It's likely that any sort of
31 excluded variables might tend to cancel out over a multi-

1 year period.

2 So just a single year's worth of data, I don't think
3 it's as serious a problem and obviously there is a
4 competing concern in terms of data quality and that's why
5 a single year's worth of data was used, but there are some
6 concerns in terms of the impact that that might have on
7 the results that are generated.

8 The Meyrick study does say that robust benchmarks
9 could be obtained using the larger data sets that are
10 available in the US. I agree, I think the real limiting
11 factor in this analysis is the underlying data, not the
12 quality of it but just the lack of it. There are only 14
13 observations available and when you only have 14
14 observations you don't have enough data to undertake more
15 rigorous sort of benchmarking techniques like economic
16 risks, you're essentially forced to use non-statistical
17 approaches like TFP indexes to construct productivity and
18 efficiency measures. The problem with those types of
19 techniques, the TFP level index techniques is that they
20 can control for these factors which are very important in
21 New Zealand, the scale of the output and customer density
22 in particular.

23 If you turn instead to US data, you have both a much
24 larger cross-section of available companies and a longer
25 time series of data and both of those things allow for
26 econometric tools to be used and that's what we were
27 trying to do, we were trying to look to alternative
28 sources of evidence, apply more rigorous benchmarking
29 techniques to that evidence and then use that to come up
30 with benchmarks for the New Zealand companies.

31 **CHAIR:** I might just interrupt you there for just a second, Dr

1 Kaufmann. You'll know from having been here we would have
2 interrupted you long by now if we didn't have to deal with
3 the video, but I would like to just stop for a minute and
4 see if anyone would like to ask questions at this point
5 rather than wait until the end, so just let me check with
6 my colleagues first.

7 **DR LAWRENCE:** You've raised quite a few issues there, and I
8 think it's probably useful if we go through some of those
9 now. Just firstly before we move on to your study.
10 Firstly a point of clarification, you raised an issue
11 regarding economies of scale and a statement that we'd
12 made actually on page 42 of my printout and we said "all
13 else equal this would provide advantage to the smaller
14 distributors". In fact what we meant there was the way we
15 model that provides an advantage to the smaller
16 distributors, if indeed there were economies of size, this
17 may be not expressed clearly in the paragraph, but it's
18 actually consistent with what you're saying, but perhaps
19 not expressed completely clearly.

20 Having said that, though, I also note that in the
21 model 3 results that you're talking about there it's
22 actually one of the small distributors, namely Envestra
23 Albury which is actually quite a small operator which
24 performs best on that measure. I think economies of size
25 are unlikely to be a major issue in that aspect of the
26 analysis.

27 If I could go back and perhaps go through quickly the
28 order of issues that you've raised there in your
29 presentation, so starting with the growth paper; you note
30 that, or you refer to NGC being a relatively small
31 proportion of the industry, it's actually 25 percent of

1 customers and a third of throughput. So I just start off,
2 as you are aware there are four New Zealand distributors
3 one of which is very small, Wanganui, that is somewhat
4 atypical, but there are three large ones. I was wondering
5 whether you thought NGC's characteristics were atypical of
6 the three large distributors.

7 **DR KAUFMANN:** I didn't notice anything atypical in terms of
8 their characteristics relative to the others, no.

9 **DR LAWRENCE:** If you're doing this sort of exercise you've got
10 the alternative of basically no information or you've got
11 a sample available that represents between a quarter and a
12 third of the industry. Wouldn't it be fair to say that's
13 a pretty good basis for getting a representative, or at
14 least an indicative result for the industry.

15 **DR KAUFMANN:** I'm not saying you shouldn't have done it, I
16 think it's fine, but I guess my concern is how much weight
17 do you put on that and can you project from that result
18 from that one company to the other two companies. In
19 terms of the -- you talked about the characteristics, I
20 think in terms of the sort of characteristics that we
21 expected for benchmarking I didn't see any differences,
22 but we didn't look at things like capital investment and
23 changes in output for the different companies and
24 obviously that's what's going to be relevant for TFP
25 growth, so I don't know how Vector and Powerco compare to
26 NGC on those counts.

27 **DR LAWRENCE:** That actually leads into my next question
28 because you actually make some comments there that the
29 company's TFP may be highly volatile from year to year. I
30 was just wondering why you made that statement because we
31 certainly don't see any evidence of that with NGC. I

1 would have thought that with distribution or utility
2 industries in general, but particularly distributors
3 they're actually characterised by very stable performance
4 over time and that's one of the reasons they're very
5 attractive to investors because they actually provide
6 quite a steady return, they're not subject to a large
7 amount of volatility, so I was just somewhat surprised by
8 that statement. Even if there is some degree of
9 volatility in a growth study we're actually calculating a
10 trend rate of growth, so any volatility that may be in
11 there is indeed removed by calculating the trend rate of
12 growth. So I was just wondering why you made that
13 statement.

14 **DR KAUFMANN:** Because I think there is volatility on both the
15 output and input side. On the output side in particular
16 for volumes. When we do gas work we're very sensitive to
17 what's happening with volumes, we examine that very
18 carefully because volumes do fluctuate from year to year
19 up and down depending on the weather in particular. So on
20 the output side that obviously matters and on the input
21 side the timing of investment can also matter, that can be
22 varied from year to year and that can impact the TFP
23 growth rate.

24 **DR LAWRENCE:** You would appreciate that with regard to
25 investment we're actually using capital stocks rather than
26 investment flows in calculating input quantities, so even
27 if there's an increase in investment the impact on that on
28 the capital stock is very muted and takes time to show up,
29 so, I don't think investment flows are a big influence on
30 TFP figures in the short term. I'd refer you to figure 1
31 in the growth report which actually plots the output

1 trends, inputs and TFP. You'll see the TFP trend there is
2 quite stable over time, it's certainly not characterised
3 by a high degree of volatility.

4 If we could perhaps move to the levels study and go
5 through the points that you've raised there. You start
6 off by talking about TFP indexes do not generally control
7 as well as econometric techniques for differences in scale
8 and I guess there's two ways of approaching this sort of
9 problem. Firstly you can have samples that are fairly
10 similar in terms of their characteristics which makes
11 these operating environment conditions such as scale less
12 important, or you can have a much more diverse sample that
13 gives you the luxury of more observations, but it makes
14 adjusting for these operating environment conditions much
15 more important, and I guess we have adopted the former
16 strategy rather than the latter and you have attempted to
17 adopt the latter in your work.

18 But while econometric techniques in principle, or in
19 theory, can adjust for some of these things I think the
20 practical experience with those sort of techniques is
21 actually quite different and I think it's fair to say that
22 experience with cost function type techniques has shown
23 that particularly multicollinearity problems really
24 severely limit the number of operating environment
25 conditions you're able to include in those sorts of
26 studies and other statistical difficulties as well such as
27 lack of variation in the data on key characteristics.

28 So I was just wondering in your experience have you
29 encountered these multicollinearity problems that have in
30 fact limited your ability to include more than a small
31 number of operating environment conditions.

1 **DR KAUFMANN:** Sometimes multicollinearity is apparent between
2 different cost drivers and if that's true then the model
3 will, when you try to include a cost driver like that, the
4 econometric will tell you that the variable isn't
5 significant. That doesn't mean that it's not really
6 significant in an economic sense, but like you say, if
7 there's multicollinearity it's hard to distinguish separate
8 impacts from two variables that are highly correlated.

9 So it's somewhat of a -- it's obviously a concern and
10 this isn't an exact science, it will never be an exact
11 science, but in terms of the amount of variables that
12 we're controlling for in our studies we're getting R
13 squareds of 98, 99 percent, something like that, we're
14 picking up almost all the variation in the dependent
15 variable. So it's not to say we're not missing some
16 things, but I think we've got a very complete model.

17 **DR LAWRENCE:** We'll come back to the statistical properties of
18 your model after your presentation. I'll just ask you
19 another question related to that. I think it would be
20 fair to say it's much more important to accurately adjust
21 for economies of size differences when you're comparing
22 New Zealand to the US than when you're comparing
23 New Zealand to Australia; in other words the New Zealand
24 utilities are much closer in terms of their size to the
25 Australian distributors than they are to the US
26 distributors.

27 **DR KAUFMANN:** They're closer, but I still don't think they're
28 all that close. I think the sample of ten from Australia
29 has two companies that are smaller than the New Zealand
30 companies and that was Albury and I believe Country Energy
31 are both smaller. There are a couple of companies that

1 are about the same size and those are the distributors in
2 Queensland, At2(?), in relative terms it's still a
3 relatively -- it's still 60 to 70 percent larger but it's
4 relatively close to those companies in terms of size. But
5 then the other five or so are much bigger, they have half
6 a million to 800,000 customers, so that really is a fairly
7 big difference in the size of operations. I think even in
8 that sample it's an important issue.

9 **DR LAWRENCE:** I was going to raise this later but seeing that
10 you've raised it now we might as well go through it now.
11 Actually in our database five of the ten distributors are
12 smaller than the larger New Zealand distributors in terms
13 of customer numbers which you identify as essentially the
14 key output variables, the largest New Zealand distributors
15 on that basis is Powerco. The largest distributor in the
16 Australian database Multinet has about six times the
17 number of customers of Powerco.

18 I think it's instructive to compare that with the
19 database you subsequently use in your study where the
20 average, well go back to the absolute values first, there
21 is only one distributor in your database, I think that is
22 Central Hudson Gas & Electric that is actually smaller in
23 terms of customer numbers than the largest New Zealand
24 distributor Powerco, and indeed the average of your sample
25 on this basis is actually eight times larger than Powerco
26 and indeed you have a quarter of your sample that is over
27 10 times larger than Powerco and your largest distributor
28 which is I think Southern California Gas is over 50 times
29 larger than Powerco, so I think that puts in perspective
30 the relative difference in sizes that we're talking about
31 between New Zealand versus Australia and New Zealand

1 versus the US.

2 **DR KAUFMANN:** Yes, and I think that's an advantage actually.
3 The fact that there is such a wide dispersion of available
4 sizes in the US from over 5 million customers of Southern
5 California Gas to about 55,000 for Central Hudson and all
6 different sizes in between does give you quite a range.
7 When you have data points that are kind of distributed
8 along that range it gives you more confidence that you
9 really are capturing the relationship between cost and
10 customer numbers.

11 Let me just say with respect to Powerco, Powerco isn't
12 in the study. I was referring to both Vector and NGC when
13 I made that comment in terms of how they compared to the
14 rest of the sample.

15 **DR LAWRENCE:** I think we'll come back to the statistical
16 implications of those very large differences in the size
17 of the distributors in the various samples after we've
18 gone through your study because they have some very
19 important implications for how valid it is to extrapolate
20 outside of your estimation range to extremely small
21 distributors in New Zealand or Australia for that matter.

22 **DR KAUFMANN:** I should add that the two New Zealand companies
23 were in our sample, we included them as well when we
24 estimated the model. So there are actually 40 US
25 companies and the two New Zealand companies.

26 **DR LAWRENCE:** But you've got two outliers in terms of the two
27 smallest companies in your sample and there are certain
28 features of the estimation procedure that you use which
29 will bias your results toward the very large end of your
30 sample, but I think we should come back to that later.

31 If we could just move on to another issue that you

1 raised; you were talking about the adjustment we did on
2 operating and maintenance costs using your earlier
3 results. I think it's fair to say that using the first
4 order coefficients to get implied output shares of costs
5 is a reasonable first order approximation, would you agree
6 with that?

7 **DR KAUFMANN:** It's a reasonable approximation to the impact on
8 total cost?

9 **DR LAWRENCE:** First order approximation is the term I used.

10 **DR KAUFMANN:** Not necessarily because I do think again that
11 the impact is going to vary from company to company
12 depending on where they start and the sort of implied
13 costs that would be needed to get them to the sample mean.
14 So I do think it depends, it depends on where the company
15 is, and the potential scale economies that they might
16 realise is moving to the sample.

17 **DR LAWRENCE:** I think you have a statement in your report
18 which I can't locate off-hand, but you sort of actually
19 draw attention to the role of the first order coefficients
20 and you actually state that they actually provide
21 important -- they have an important role in your model --

22 **DR KAUFMANN:** They do.

23 **DR LAWRENCE:** -- in terms of providing a reasonable
24 approximation to the results of the sample mean.

25 I think you also made the point regarding second order
26 coefficients and perhaps it would be desirable to include
27 those. I think, if I'm correct, in your model you
28 actually normalise the data relative to the mean for each
29 variable, is that correct?

30 **DR KAUFMANN:** Yes, we do.

31 **DR LAWRENCE:** I think that greatly reduces the importance of

1 second order coefficients, it means that you will be
2 picking up most of the relationship from the first order
3 coefficients.

4 **DR KAUFMANN:** It does blunt the impact, yeah.

5 **DR LAWRENCE:** You also raised the issue of O&M costs versus
6 total costs and indeed you'd be aware that, I think I'm
7 correct in saying that from the published, or the report
8 that we had available from your Australian study we were
9 only able to obtain the relationship for total cost, I
10 think I may be -- correct me if I'm wrong, but I think to
11 actually get the O&M relationship we would actually need
12 the data for the utilities as well as the actual
13 coefficients.

14 **DR KAUFMANN:** I don't believe that's correct because the study
15 we did for them was an O&M benchmarking study I believe,
16 from recalling correctly. So we did have the total cost
17 coefficients and we also had the O&M cost share
18 coefficients there. So it would have been possible, it
19 would have been messy but --

20 **DR LAWRENCE:** Certainly much more complicated.

21 **DR KAUFMANN:** -- it's possible, yeah.

22 **DR LAWRENCE:** I think would it be fair to say, though, that
23 O&M costs are mainly influenced by customer numbers rather
24 than throughput?

25 **DR KAUFMANN:** Yeah, I believe that's true.

26 **DR LAWRENCE:** It's fair to say that using the total output
27 relationship is going to be a reasonable approximation for
28 the O&M cost relationship?

29 **DR KAUFMANN:** Yes, leaving aside the issue of scale economies.

30 **DR LAWRENCE:** Okay, can we just move on quickly to the issue
31 of using the AGLGN benchmark, or using that as a sort of a

1 numerare(?), if you like, for normalising the customer and
2 energy densities; I think you would have to agree it's
3 sort of a common technique in benchmarking approaches,
4 particularly multi -- well, it's actually a feature of
5 multilateral index approach that you actually compare
6 everything relative to an average of the sample, that's
7 how the technique works, that's how it makes it invariant,
8 so what we're doing is essentially roughly consistent with
9 that indexing procedure that we're using to calculate the
10 productivities in the first place. I acknowledge that
11 it's quite different to a cost function based approach but
12 it needs to be, to be consistent within this particular
13 methodology that we're using.

14 **DR KAUFMANN:** Yeah, it is true that in the multilateral TFP
15 method that -- it is expressed relative to the sample
16 mean, that's correct.

17 **DR LAWRENCE:** You make some comments about hypothetical
18 benchmarks and how that's different to using own data, but
19 I'm a little bit confused by that because the way you
20 report your own results essentially utilises the
21 hypothetical concept. In other words you're reporting
22 your actual costs relative to a predicted cost based on
23 your sample, which is itself a hypothetical construct, or
24 hypothetical figure. So I'm just a little bit confused
25 there. It's fair to say you're using essentially a
26 similar hypothetical concept.

27 **DR KAUFMANN:** I think that's an important point. I think
28 there is a real distinction. Because what we're using, is
29 we're making -- our approach does make estimates of the
30 fundamental cost drivers, or the relationship between cost
31 and various variables that are driving cost and that is

1 what we try to estimate, and I think that's fundamental.

2 But what we do then -- and that process does construct
3 a hypothetical, I suppose you can say, cost measure for an
4 average firm, but what's important about that is that
5 hypothetical cost measure can be tailored to reflect the
6 individual conditions of each firm, so what's fixed in
7 your approach are the coefficients themselves, the
8 underlying cost drivers, what's inherent in the technology
9 that relates cost to the variables. That's what's fixed
10 and that's what we hold fixed and that's what we estimate
11 and then we take the data from the company itself, that
12 goes into the model and those data reflect the company's
13 own conditions and then the model projects a cost figure
14 which again is tailored to the company's conditions and
15 all the interactions between those business conditions.

16 In that sense that's the difference, the benchmark
17 that comes out at the end reflects the company's own
18 conditions and not the conditions of the sample mean.

19 **DR LAWRENCE:** The point is they both use a hypothetical
20 construct and there are different ways of getting to, if
21 you like, a way of trying to standardise for a range of
22 operating environment conditions, or in this case customer
23 and energy densities within the sample.

24 **DR KAUFMANN:** Yeah, a benchmark is a hypothetical construct,
25 any benchmark will be. I think the real issue is does the
26 benchmark reflect the company's own conditions.

27 **DR LAWRENCE:** We might just move on. You also make some
28 comments, I think you acknowledge this in your
29 presentation about the trade-offs involved in using a
30 single year's data versus multiple year's data. I think
31 some of the comments you make in your paper reflect, if I

1 can put it this way, a North American perspective, where
2 you've got the luxury of a much larger database over quite
3 a number of years, it's much more mature, it's much more
4 stable.

5 I think you'd be well aware that in New Zealand and
6 Australia we don't have that luxury because the data is
7 still in its relative infancy and it's still being refined
8 quite rapidly over time, so I think you would have to
9 agree that it's a reasonable approach to use the most
10 recent year's data in that circumstance because it's going
11 to be much better quality, it's going to be much more
12 refined and hopefully more accurate data than
13 earlier year's data which, particularly in terms of asset
14 valuations and the like, is still quite variable.

15 **DR KAUFMANN:** Yeah, I absolutely agree with that. That's not
16 a major point, I think that's a very reasonable sort of
17 approach to take in general.

18 **DR LAWRENCE:** I think that's the major points I had at this
19 point.

20 **CHAIR:** Why don't we proceed then, Dr Kaufmann, with the
21 presentation, I believe we're on slide 13, is that
22 correct?

23 **DR KAUFMANN:** Yes, that's right. I've already talked a little
24 bit in general terms about our benchmarking approach and
25 I'm not going to go through all the gory details of this,
26 but I do think it's important to try to give the
27 Commission a better understanding of exactly what it is
28 we're doing so that hopefully you can have some confidence
29 in what ultimately comes out of the process.

30 So I am going to go through this and touch on a few
31 technical details here and there just to present those and

1 to kind of put those on the record and give you something
2 to mull over in terms of what it is that we're actually
3 doing. Basically what we've done is we've developed an
4 econometric cost model and that cost model relates cost as
5 the dependent variable to three sets of independent
6 variables or cost drivers, and those three sets of
7 variables are outputs, input prices and business
8 conditions, other business conditions.

9 This is a very well developed sort of approach, it
10 comes right out of economic theory, so it's got a very
11 strong grounding in the literature. Then given that sort
12 of basic model what we've done is we've estimated that
13 model with US gas distributor data and what we attain is
14 estimates of the underlying cost drivers, so the impact
15 that changes in output, changes in input prices and
16 changes in these other business conditions have on a
17 company's costs. This basic approach has been used and
18 accepted in a number of regulatory proceedings that we've
19 been involved in and others as well in the US, Canada and
20 Australia and increasingly in other countries as well.

21 Turning to slide 14 the basic data that we used, again
22 we've been developing this database for over ten years and
23 it's different than the electricity industry in the US in
24 that there's not a centralised source of data that you can
25 go to. In the electricity industry FERC collects FERC
26 Form 1 data, it's been doing it for 50 or 60 years, so
27 there's a very solid and well accepted sort of template
28 and series of data for the entire industry.

29 That's not really the case for gas. You can look to
30 different publicly available sources but you have to look
31 in a lot of different places and pull the data together

1 and that's what we've done, relying on a number of sources
2 like uniform statistical reports which was a file that
3 companies used to file fairly regularly and many don't any
4 more.

5 A number of State Regulators have separate mandatory
6 data filings for their gas distributors and in those cases
7 we get those reports from the State Regulators, and FERC
8 does have something called FERC Form 2 which is for the
9 gas industry but it's limited because it's -- that only
10 refers to companies that are FERC regulated, so there it
11 would be companies that have some interstate gas
12 operations which is a relatively small subset of the
13 industry.

14 So we've been developing this database from a number
15 of sources and checking and rechecking, it's not at all
16 uncommon for us to use two different data sources for the
17 same company and check and double check figures against
18 each other just to make sure that we have real confidence
19 in the underlying data.

20 So right now our database includes about 40 companies
21 that we feel have quality data and it's a very
22 heterogeneous sample in terms of things like size of the
23 companies, input prices they face, the different regions
24 in the country that they operate in, and other things like
25 that, customer density, urbanisation, factors like that.

26 On slide 15 this actually presents the sample of
27 companies that we use and Denis has already talked about
28 some of these companies and some of their characteristics,
29 for example you've got companies as large as Southern
30 California Gas with over 5 million customers. The smallest
31 company in our sample is Central Hudson which is about the

1 size of Vector and NGC, but as you can see there aren't
2 many US companies that are about that size.

3 Even though it's only 40 companies, that still
4 accounts for over 52 percent of customers and even more of
5 that in terms of volumes served in the industry, so we
6 feel that it's fairly representative as well but obviously
7 not completely representative.

8 Moving to slide 16, one of the things we tried to do
9 was to come up with a measure for gas distribution costs
10 that was comparable with the measure that's been
11 considered in this inquiry. And that measure would
12 include the gas distribution service itself and also meter
13 ownership, but it would exclude meter reading billing and
14 collection and other costs that are related to retailing
15 operations and that's the measure that we constructed for
16 the US companies. The database that we have is
17 disaggregated enough that we can take out meter reading
18 costs, billing collection costs, other things like that
19 and we did in fact remove those costs which we'd otherwise
20 include in our distribution measure. We took those out of
21 the cost measure so it was comparable to the cost measure
22 that's being considered here.

23 Administrative and general costs, both expenses and
24 plant, we allocated those to between gas and other
25 operations, particularly electricity, based on relative
26 share of expenses, of the non-administrative and general
27 expenses so that they were proportionate.

28 Moving to slide 17, capital costs, we followed a
29 fairly standard sort of approach to measuring capital
30 costs and again we have to construct -- cost is our
31 dependent variable, so we do have to consider the costs

1 associated with capital ownership as well as O&M costs
2 when we're evaluating overall performance. What we did is
3 we have a quantity of capital in a given year and then we
4 multiplied that by a capital service price that applies in
5 that year, we constructed the quantity of capital through
6 this equation that's the third from the bottom on this
7 page, this is sometimes called perpetual inventory
8 approach to capital accounting, and essentially all you're
9 doing is you're taking the capital stock in the last
10 period, taking off depreciation, adding investment to it
11 and then deflating that investment by a deflator that
12 reflects inflation since the base year. We've been doing
13 that -- our capital addition series goes back about 20
14 years so we have a base year capital in 1983, we add up
15 capital addition, we apply this formula to capital
16 additions since 83 and develop a capital stock in all of
17 those later years.

18 The asset price deflator we use is something that's
19 estimated from a company called Handy-Whitman which
20 develops a number of different indexes for construction
21 and asset price inflation for different utility industries
22 and we use the Handy-Whitman index for gas distribution to
23 deflate the capital additions.

24 On slide 18 we used a very simple user cost of
25 capital -- sorry, a capital service price in this study
26 which just has three components. The first component
27 there reflects the opportunity cost of capital;
28 essentially it's like the return on capital, it's very
29 similar to that. The second component reflects
30 depreciation and then the third component is capital
31 gains. All that is is the change in inflation from year

1 to year. This is something again that kind of comes out
2 of theory that says that there should be this capital
3 gains component. We smooth that so that we actually take
4 a moving average of capital gains over the time period.
5 Then we apply the same deflator, the Handy-Whitman
6 deflator so it also reflects inflation as well.

7 So that's our cost measure, the sum of capital costs
8 and O&M costs, again tailored to be consistent with the
9 set of services that are considered in the inquiry, and
10 for the independent variables or the cost drivers, on the
11 output side we've got customer numbers and volumes which
12 are the same outputs that were used in the Meyrick study.
13 Input prices, we've got the capital service price that I
14 just mentioned, the price of labour which here is an
15 employment cost index for the US electric gas and water
16 sector, that comes from the Bureau of Labour Statistics.

17 The price for other inputs is a very difficult thing
18 to pin down. There are some companies that estimate that,
19 but we found that those rates of -- if you use those sort
20 of tailored estimates they don't really vary too much
21 from, say, broader inflation measures like change in the
22 GDPPI. So we just use GDPPI as the deflator for other O&M
23 inputs. We apply that same deflator to all companies.

24 Then there were two other business conditions in this
25 model, one is the miles of distribution main and this is
26 designed to pick up the customer density issue. If you
27 have both customer numbers and miles of main in the model
28 then by having both of those in the model then you're
29 considering the relationship between customers per miles
30 of main, so you don't need to have that explicitly. We've
31 got them both in there so we're accounting for customer

1 density. Also because we have volumes in customer numbers
2 we're also accounting for energy density or volume per
3 customer.

4 Then finally the percent of main that is not cast
5 iron, we found that having a very cast iron intensive
6 system can be very costly, those were typical of very old
7 systems, they leak a lot and have higher maintenance
8 costs, so we include that as an independent variable as
9 well. The reason this variable isn't percent of main that
10 is cast iron, is that there are some companies out there
11 that have no cast iron at all, it just so happens if we
12 use a value of zero our model won't accept a value of zero
13 because it's a log model and the log isn't defined at a
14 value of zero.

15 Let's move on to slide 20. This is the cost function
16 itself and --

17 **CHAIR:** Our non-economists are enjoying this slide a lot.

18 **DR KAUFMANN:** I thought they might. This looks like kind of a
19 beastly thing, but --

20 **CHAIR:** We're going to let Commissioner Bates who's a lawyer
21 ask the questions on this slide Dr Kaufmann.

22 **DR KAUFMANN:** Okay. Let me just explain some of the intuition
23 behind this and not grind through the math, but what this
24 is designed to do is it's designed -- you have to have
25 this type of complexity if you're going to pick up
26 economies of scale, for example, because when you're
27 talking about economies of scale you're not talking about
28 a linear relationship. You've got costs on the one hand
29 and output on the other and at very low output levels,
30 costs rise relatively slowly and then they start to rise a
31 little bit faster as you start to approach the minimum

1 scale, so you need something that reflects that
2 relationship, you need non-linearities and you also need
3 to consider the interaction between these different
4 variables. It's not just the amount of variables, but the
5 mix, or the amount of outputs, for example, that companies
6 are providing but the mix of outputs. You need to
7 consider that to really get at customer energy and energy
8 density, for example.

9 What we have here is this first line just reflects
10 what Denis was referring to earlier as the first order of
11 conditions. We've got on the left-hand side we've got
12 costs as the dependent variable and then on the right-hand
13 side we have all these cost drivers and that first line
14 reflects the first order term, so this, if we stopped at
15 this line it would be a log linear model, but all the
16 stuff underneath that reflects the interactions between
17 outputs and the -- what are called the quad rat I can
18 terms in outputs are essentially the square terms.

19 So just to let you know that this is the model we
20 used, it's a very well-defined, well accepted kind of
21 model, in fact it can be shown that this model is an
22 approximation to any underlying production technology, and
23 that's really the real fundamental rationale for using
24 this, is that it doesn't restrict the underlying
25 technology. We don't really know the underlying
26 technology and how firms are combining inputs to produce
27 outputs. It just so happens this cost function which is
28 called the translog cost function is a very flexible and
29 non-restrictive sort of approach that doesn't restrict
30 that underlying technology.

31 Slide 21, and this I promise is the last technical

1 kind of slide, but again just to let you know what it is
2 that we did, what we actually estimate is a system of
3 equations, so we have cost and we also have the share
4 equations for O&M and for capital costs. Those are again
5 developed through a well developed approach called
6 Sheperd's lemma and we estimate all three of those things
7 simultaneously. There are good reasons to do that as
8 well.

9 But one thing I'd like to point out, and it may not be
10 recognised and in fact I don't think I really made
11 explicit mention of it in the report is that we have an
12 estimation procedure that's designed to control for
13 something that's called heteroskedasticity, and what that
14 means is that the variance terms of the errors differ from
15 company to company. In general if you have
16 heteroskedasticity, if your information procedure suffers
17 from heteroskedasticity then you're not going to be making
18 proper inference on the coefficients on what's a
19 significant cost driver and what isn't.

20 This is important, and the reason I'm telling you all
21 this, is because we do have a very heterogeneous sample
22 and when you have a sample that's that heterogeneous then
23 you might expect that even after you -- you might expect
24 that the variance of the error terms that are associated
25 with any individual observation in the sample are going to
26 differ from company to company, it's a legitimate concern.

27 So we developed an estimation procedure that controls
28 for heteroskedasticity. There's well developed ways of
29 doing that, but usually only in a single equation case, so
30 if you're only estimating a single equation. It took a
31 long time for us, in fact we had an econometrician working

1 on this for about a solid two months to work out the right
2 way to implement heteroskedasticity corrections in a
3 multi-equation system. So just to let you know that we do
4 have a procedure here that's designed to control for what
5 might be considered a potential problem with applying
6 econometrics to these samples. That's the end of the
7 technical discussion.

8 Slide 22, here are the results that result when you
9 apply this translog model to the data that we used, and we
10 do have the first order terms here highlighted. So let's
11 go to the right column first and at the top there we've
12 got N, and N is the customer numbers. That coefficient
13 there, just on that first order term, represents the
14 estimated impact of a 1 percent change in customer numbers
15 on a company's total cost, holding everything else
16 constant. That's also true for each of these other
17 coefficients, the first order coefficient. The same thing
18 on V which is the impact of volumes, that coefficient,
19 0.071, again that's the percentage impact on estimated
20 cost of a 1 percent increase in volumes.

21 You can see that the number of customer coefficient is
22 quite a bit bigger than the volume coefficient which
23 indicates that customer numbers is a much bigger cost
24 driver than volumes, and in fact the relative proportions
25 of these two outputs as cost drivers is similar to the 86
26 percent that we found in the Victoria study and that Denis
27 mentioned before.

28 One other thing I should mention is that the Victoria
29 study did not use that heteroskedasticity corrected
30 estimation procedure. I tend to think of that as
31 obsolete. We implemented that, it worked for Boston Gas

1 in 2002, 2003, and all our work since then uses that
2 procedure.

3 The coefficient on NI, that's the coefficient on the
4 non-cast iron variable, and that's negative. All of these
5 are significant, by the way, they're all statistically
6 significant. So what that indicates is that as your
7 system becomes less cast iron intensive, as the percentage
8 of your pipes that are not made of cast iron declines,
9 then your costs go down. So your costs decline as your
10 sensitivity -- as the percentage of cast iron pipes -- as
11 the percentage of non-cast iron pipes increases then your
12 system becomes less cast iron intensive so you have lower
13 costs associated with that.

14 That's the same thing as saying that cast iron pipes
15 are costly. If you have more cast iron then costs will
16 increase.

17 **CHAIR:** What's the logic for the relatively low parameter
18 estimate on volume? Why do you think you get that result?

19 **DR KAUFMANN:** I think if you step back and you think about a
20 gas distribution network and what's really driving the
21 cost it mostly does depend on the customers and where
22 they're located. Essentially you would lay a distribution
23 main and then you'd have services coming off that main
24 with meters associated with each customer and those costs
25 are mostly fixed and they're mostly driven by the
26 customers that you're serving and where those customers
27 are located.

28 **CHAIR:** Isn't this being driven mostly by customer numbers?
29 Am I not reading this right?

30 **DR KAUFMANN:** Yes, that's right. It's being driven by
31 customer numbers and that last variable in that column,

1 that's the miles of distribution main, that's the
2 coefficient on the positive distribution. So these are
3 the two main things that are driving on the output and
4 location sort of issues. It's the road sort of analogy
5 that Denis uses sometimes, that the real costs are with
6 building the road and the traffic that comes down the road
7 doesn't have that much impact on the company's cost. The
8 volumes there are obviously the traffic and the road.

9 On the other side, the left-hand column the first
10 shaded term is the price of labour and the second shaded
11 term is the price of capital. Again, the interpretation
12 of these is that this is how much costs would increase
13 given a 1 percent change in these variables, holding
14 everything else constant. You can see the price of
15 capital has a much bigger impact than the price of labour
16 because these are in fact capital intensive businesses,
17 most of their costs are driven by capital.

18 The other variables there, these are interactions
19 terms and square terms, so these are the other sort of
20 elements of the translog cost formula. But just looking
21 at the shaded terms and the business condition terms gives
22 you -- it kind of conveys the real, I guess the essence of
23 the model but -- it's certainly not unimportant that there
24 are these other terms because those other terms do drive
25 the relationship between costs and economies of scale for
26 example, so they're all there, they're playing an
27 important role but just to kind of give the essence of
28 what we have, you can just look at the first order terms.

29 This final number on the right-hand side, that's the
30 system R^2 , that's the R square, that's the
31 fraction of the variation in cost that's captured by the

1 variables on the right-hand side. That's going to be a
2 number between 0 and 1, so as it approaches 1 -- if you
3 had a number equal to 1 that means you're capturing 100
4 percent of the change of cost, in this case, by the
5 variables you're considering, and you can see here we're
6 capturing about 97 percent of the change in costs by the
7 variables in our model.

8 **CHAIR:** Why on the first order volume estimate would you not
9 expect it to be negative? Wouldn't you have expected, as
10 volume increases, costs to reduce? Am I looking at that
11 wrong?

12 **DR KAUFMANN:** You're thinking of the second order term in a
13 sense, and that is negative, if you look at the VV
14 underneath it, that's a negative term. I think what
15 you're thinking there is kind of the relationship between,
16 say, volume per customer, holding customers constant, then
17 if you increase volumes so one company has more volumes
18 per customer than another, that's kind of the VV term and
19 that is in fact negative.

20 So those are the results from our econometric model
21 and turning to slide 23 we then applied this model to the
22 New Zealand companies by taking these parameter estimates
23 and then taking specific values for each of these business
24 conditions, price of labour, price of capital, customers
25 throughput, percentage of main that's not cast iron and
26 miles of main and all the interactions between those
27 things; we put those exact values into the model and then
28 we generated a cost prediction.

29 So for that part of the exercise we got data from the
30 companies on each of these things and tried to divide
31 things as comparably as we can between the US and

1 New Zealand to make sure that we have the most appropriate
2 measures there and then we took each of those variables
3 and placed them in the model and generated a prediction
4 and a T-statistic which you can use to judge the
5 statistical significance of that prediction.

6 For customers and volumes those are pretty
7 straightforward, defined pretty much the same in the US
8 and New Zealand, kilometres of gas main and percentage of
9 main that's non-cast iron, again pretty straightforward.
10 The labour price measure that we used, that was data from
11 Statistics New Zealand on the electric gas and water
12 sector wages.

13 For other O&M prices what we did was looked to data
14 from Mercer which is an international executive placement
15 company and they have a number of data on what the cost of
16 living is in a number of cities throughout the world and
17 it's all expressed relative to New York and there was data
18 on Wellington and I believe Auckland, and we used that
19 data to construct relative cost of living indexes relative
20 to our US sample and New Zealand and then we used that as
21 the basis for the O&M price level. So that's how we
22 linked to O&M prices in the US, to other O&M prices, to
23 other O&M prices in New Zealand.

24 **CHAIR:** What does the Mercer study use, the current exchange
25 rate, is that what it does?

26 **DR KAUFMANN:** I'm not sure, it's expressed in index numbers
27 and it looks like a PPP type of rate.

28 On slide 24, this is the capital service price and
29 what we did there is we -- there are three elements of
30 that price that we needed to develop that for New Zealand
31 and then to link that to the US. One is to come up with a

1 rate of return, and what we did there is we looked to the
2 economy-wide return to capital for the New Zealand
3 economy, we computed that using national income account
4 data. Depreciation, we assumed that was equal to 4.5
5 percent, I believe that's the same assumption that was
6 used in the Meyrick study and we also again needed to link
7 this on a levels to levels basis with the US, and there is
8 a company called Richardson which is an engineering
9 company which has compiled a lot of data on the cost of
10 building different types of facilities in different parts
11 of the world and they don't have any data for New Zealand,
12 but do have data for Australia, again expressed relative
13 to the US.

14 So what we did as a first cut at this was to take the
15 Richardson data on construction cost levels in Melbourne
16 relative to the US and we used that as an estimate of the
17 differences in construction costs between the two
18 countries.

19 **CHAIR:** There's nothing in the national accounts that would be
20 more appropriate to New Zealand?

21 **DR KAUFMANN:** We didn't see anything. We couldn't find
22 anything more appropriate. I should say, though, that we
23 were a bit under the gun for this study, we didn't have as
24 much time to investigate all these issues as we normally
25 might.

26 **CHAIR:** I wouldn't necessarily think the construction costs
27 would be similar for Melbourne and New Zealand; but you've
28 done sensitivity analysis, does it make much difference?

29 **DR KAUFMANN:** No, it doesn't, that's right. So we did a
30 sensitivity analysis where we assumed no construction
31 costs differentials between Australia and New Zealand.

1 What Richardson actually shows is that construction costs
2 tend to be much higher overseas than in the US when you
3 factor in differences in productivity of labour, that
4 tends to raise construction costs overseas. So the
5 Richardson data showed that construction costs are higher
6 in Melbourne and our sensitivity was essentially to assume
7 that away and to assume that construction costs were the
8 same.

9 **CHAIR:** That translation of those construction costs in
10 Melbourne to the US were done on what exchange rate
11 assumption?

12 **DR KAUFMANN:** That's on a purchasing power parity exchange
13 rate. In fact the model does generate predictions in US
14 dollars, it's estimated with US data so it's going to give
15 you a US dollar prediction for costs. What we did then is
16 we compared that prediction to the company's costs which
17 was converted to US dollars using the purchasing power
18 parity exchange rate.

19 **CHAIR:** I just ask that question because when we've done this
20 work in telecommunications the result is practically
21 driven by what exchange rate you choose to adopt. To say
22 we have had extensive debate on that is an understatement.

23 **DR KAUFMANN:** We did look at the exchange rate that was used
24 in that decision, and if we would have used that rate the
25 company's actual cost in US dollars would have been about
26 20 percent lower.

27 **CHAIR:** I'm not surprised. I saw that in the paper I'm not
28 surprised. It makes a big difference to the result. We
29 had contended for the spot rate or the PPI which even
30 increases the difference more, but anyway, please go
31 ahead.

1 **DR KAUFMANN:** Okay. Slide 25 presents data on each of these
2 variables, for the US and for the two New Zealand
3 companies. What this slide shows is the values for costs
4 and each of the cost drivers for the US relative to the
5 two, well both the US sample average and how the two
6 New Zealand companies compare to the US. It's pretty
7 clear that these two companies are quite small relative to
8 the average US company, 6 and 8 percent of customers
9 served, 5 and 8 percent of the computed gas delivery
10 costs. So that implies that the cost per customer is
11 lower, or equal, for the New Zealand companies compared
12 with the US sample average, without controlling for
13 anything else.

14 The total throughput, even smaller than customers
15 relative to the US, 4 percent and 5 percent. That implies
16 that volume per customer is lower in New Zealand than in
17 the US. If we kind of go to the entry, the second to last
18 entry from the bottom, the miles of distribution main,
19 there we've got 14 percent for NGC and 26 percent values
20 for miles of main relative to the US.

21 That indicates that since that is so much greater than
22 the customer fraction, that miles of main per customer for
23 both of the New Zealand companies is much greater than for
24 the US companies. So that's equivalent to saying that
25 there's less customer density for the New Zealand
26 companies than in the US sample. Both customer density
27 and volume density are factors that tend to work against
28 companies, so it's important to control for those and both
29 of the New Zealand companies are disadvantaged by those
30 factors compared to the US sample.

31 Looking to price of capital, price of labour, price of

1 materials, price of labour and price of materials are
2 similar. Materials are a little bit lower, reflecting a
3 slightly lower cost of living in Wellington compared to
4 the US, at least according to Mercer and price of labour
5 slightly higher. That surprised me a little bit, but I
6 think that might reflect the fact that there's been much
7 more out-sourcing -- in part there's been much more out-
8 sourcing in New Zealand than in the US industry, so the
9 composition of the workforce that remains tends to be
10 managerial and higher skilled and higher paid.

11 **CHAIR:** Those costs in the US must vary very significantly
12 across the US don't you think?

13 **DR KAUFMANN:** Sorry, I missed that.

14 **CHAIR:** You use an average for the US on these costs or
15 prices, they must vary very significantly across the US,
16 is that right?

17 **DR KAUFMANN:** They do, that's right.

18 **CHAIR:** Does that cause us any concern?

19 **DR KAUFMANN:** This is just kind of descriptive data, just to
20 give you a sense of the average in the US and the two
21 companies. What might be most surprising here is the
22 price of capital services that shows that it's quite a bit
23 higher in New Zealand than in the US. That is mostly
24 driven by the Richardson assumption on higher construction
25 costs in Melbourne, again we tested the sensitivity of
26 that.

27 **CHAIR:** I think Commissioner Bates had a question Dr Kaufmann.

28 **MS BATES:** I just wanted to clarify with you what you said
29 about the price of labour and I think I understood you to
30 say that it was higher in New Zealand than in the US,
31 right?

1 DR KAUFMANN: Correct.

2 MS BATES: You thought that was because of out-sourcing?

3 DR KAUFMANN: Yes, this is the price of labour in the
4 industry, that's right.

5 MS BATES: But does it matter -- I mean you mean out-sourcing,
6 work to be done by contractors obviously?

7 DR KAUFMANN: That's right.

8 MS BATES: Does it matter whether the labour is supplied
9 inside or outside of the company, because you still have
10 to engage the labour whether it's in-house or not in-
11 house?

12 DR KAUFMANN: That's right, a lot of those out-sourcing
13 contracts obviously are labour but this is a labour -- but
14 the companies report that as other O&M expenses, so this
15 is a labour measure, as I understand it, within the
16 industry that reflects the labour employed in that
17 industry and not out-source labour.

18 MS BATES: Where is it picked up in this then, in your table?

19 DR KAUFMANN: What, the out-sourcing?

20 MS BATES: Yeah.

21 DR KAUFMANN: That's reflected in other O&M costs, and here
22 the price of those other O&M costs is the price of
23 materials.

24 MS BATES: So that comes in there, right?

25 DR KAUFMANN: That's right.

26 MS BATES: So is the price materials correspondingly different
27 in the US?

28 DR KAUFMANN: Yes. The measure that we're using here is a
29 lower price of materials in New Zealand.

30 MS BATES: Thank you.

31 DR KAUFMANN: Turning to slide 26, I think we've already gone

1 through that, the table shows that the importance of scale
2 and volumes per customer and customer density, all those
3 things are very important to control for in a benchmarking
4 model because there are such differences in the scale of
5 output, and to a lesser but still important extent there
6 are differences in customer density and energy density
7 between the New Zealand companies and the US companies.

8 On slide 27 this is the result of our model where we
9 inserted these various cost drivers into the model and
10 came out with cost predictions. The model also produces
11 T-statistics which are testing the statistical
12 significance between any difference between what the model
13 predicts as cost and what the companies actually have as
14 cost.

15 You can see that, and we did this for the entire 1997
16 through 2002 period for both NGC and Vector, and you can
17 see that for both NGC and Vector our model shows that
18 after you control for these very important factors like
19 scale of outputs and customer density and things like
20 that, that the predicted cost for each of these companies
21 is lower than the actual cost that they have and that
22 difference is statistically significant. For Vector it's
23 21 percent lower and for NGC it's 30 percent, just over 30
24 percent lower.

25 That result implies that these companies are effective
26 in keeping their costs below what would be expected. Here
27 below what would be expected, this is kind of the
28 benchmark, this is the cost that an average US gas
29 distributor would have if it faced the same exact business
30 conditions as these companies. So an average gas
31 distributor, if it was operating in NGC's system, would

1 have costs about 30 percent higher. Vector, again an
2 average US gas distributor would have costs about 2
3 percent higher for Vector's system. That was the result
4 that we obtained using the model.

5 Slide 28, this records some of the sensitivities that
6 we considered. We start with the base case predictions
7 and consider the one scenario we already talked about
8 which is there's no differential between construction
9 costs in New Zealand and the US, and we also looked at
10 differences in the opportunity cost of capital, or -- I
11 didn't use this term and I hesitate to use this term --
12 but differences in the WACC, this is what I'm really
13 talking about here and whether that would really make much
14 difference for the results.

15 In all these cases what we found is that those changes
16 had very little impact on the results. NGC stayed close
17 to 30 percent below predicted cost, Vector stayed 20 to 21
18 percent below predicted cost, so the results aren't
19 sensitive to those assumptions, the results are robust to
20 changes in those assumptions.

21 To conclude on the last slide, what we were asked to
22 do in this proceeding was to provide some evidence on the
23 company's efficiency using what I consider to be more
24 robust techniques and techniques that are really designed
25 to control for issues that are very important for these
26 companies, like economies of scale and customer density.
27 Econometrics is able to do that, the multilateral TFP
28 indexes can't do that nearly as well, and our results show
29 that NGC and Vector are in fact pretty good cost
30 performers, very good, significantly below what would be
31 expected for a US firm.

1 That conclusion isn't really affected by the
2 assumptions we've made on the capital service price or
3 exchange rates. If we used different exchange rates then
4 that 20 and 30 percent would be something more like 40 and
5 50 percent.

6 **CHAIR:** Can I ask you, Dr Kaufmann, when you look at the
7 results for the US companies that either significantly
8 under-perform or over-perform from the average, what's the
9 variation look like for those that are significantly
10 better performers or under-performers, how much variation
11 are you seeing across the US companies?

12 **DR KAUFMANN:** There are about 40 companies in our sample and
13 if the model is telling us that any company is more than
14 say 30, 35, 37 below predicted cost we tend to question
15 the model, that just doesn't seem like a plausible sort of
16 result. And in fact that's what we tend to find in this
17 model, is that a result of close to 30 percent below
18 predicted cost is just about -- that's at the high end of
19 what we're seeing for the US companies, there are one or
20 two US companies that are a bit higher than that, but
21 similar, and on the other side there are some companies
22 that are 20 to 25, 30 percent above predicted cost; so
23 it's fairly symmetric in that sense.

24 You can divide the sample in three types of companies
25 in terms of the significance of the results. There's
26 going to be a number of companies that are grouped
27 around -- where their actual costs are equal or close to
28 their predicted cost and you're not going to be able to
29 find any statistical significance in the difference
30 between actual and predicted cost. Those bounds tend to
31 be within 8 to 10 percent, so if you're within plus or

1 minus 10 percent of predicted cost, that tend to be the
2 range in which -- you can't really discriminate between
3 actual and significant costs, or actual and statistically
4 different predicted cost.

5 In terms of, say, the sample of 40, I think about 15
6 companies or so tend to be in that range, so we find about
7 15 out of 40 companies are about what you'd expect, and
8 maybe 10 or so, 10 or 12 are significantly superior and 10
9 or 12 are significantly inferior.

10 **CHAIR:** How do you decide that a company was showing actual
11 costs 35 percent lower than what you predict would cause
12 you concerns about the model, but if it's up to 30 it
13 doesn't? I mean what is it about 35 as opposed to 30 that
14 says to you you'd want to think again about your model?

15 **DR KAUFMANN:** Well, there are a number of things that go into
16 evaluating a model when we think about it, that's just one
17 of them. It's just kind of a reality check or a sanity
18 check to see if you're getting results that seem
19 plausible. Anything beyond say -- it is a judgment call.

20 **CHAIR:** What's plausible about 30 percent that isn't plausible
21 about a 35 percent difference?

22 **DR KAUFMANN:** It's a judgment call, there has to be some
23 number at which things start to look implausible.

24 **CHAIR:** Sure, but it's based on something that judgment, the
25 point at which you get concerned about the realism of the
26 results. This is very significant variation across this
27 study, isn't it?

28 **DR KAUFMANN:** It's within the range of what we see in the US.
29 I guess I would say it's kind of years of doing this and
30 kind of seeing what come out of these models and what
31 seemed to be a plausible range in models that are behaving

1 well and what seem to be results that look implausible for
2 models that we know aren't behaving well, so it's kind
3 of -- I just have to say it's a judgment based on years of
4 experience of looking at these things.

5 **CHAIR:** I guess that you get that range when you look within
6 the US, but when you think about the difficulty in coming
7 up with comparative data across border, not to mention
8 problems like exchange rate and other things, you start
9 feeling a little bit more nervous even about the outliers
10 that happen to be the two companies from outside the
11 jurisdiction where you have to make your -- your input
12 data isn't probably as comparable, you've had to use far
13 more -- you've had to look and try to find comparative
14 data, but how close you get is a question, and you've done
15 sensitivity testing. But I always find these studies very
16 hard to deal with from a regulatory perspective, having
17 been through long debates in other industries on these
18 things, it's very troubling because in every hearing you
19 get completely opposite results presented to you depending
20 which side is presenting.

21 I guess my question to you really is, I mean you've
22 made the comment that these approaches are used in the US,
23 but I'd be most surprised if -- even though it's accepted
24 to look at benchmarking and that it's used and we all
25 reach to these things, I'd be most surprised if there
26 weren't extreme debates going on about the actual results
27 beyond just the general model and its application. Is
28 that a fair comment about the US regulatory debates that
29 happen on benchmarking as well?

30 **DR KAUFMANN:** I think any time benchmarking is introduced
31 anywhere there's going to be debates and unfortunately

1 it's a technical issue and I think you're right to be a
2 bit skeptical of any benchmarking result. I say that, I
3 don't have any problems saying that, I do these things all
4 the time; I'm not necessarily an advocate of benchmarking,
5 I think benchmarking can be done well, it can be done
6 badly, it can be used well, it can be used badly.

7 I think you have to have some understanding of the
8 quality of the study and you have to interpret the results
9 of the study with care. I think that might be one of the
10 points is that I was trying to reach to data that allowed
11 for a more rigorous sort of benchmarking technique that in
12 turn I think would lead to more reliable and robust
13 results.

14 **CHAIR:** You said that you were a bit pressed in terms of
15 timing to do this; if you had more time what would you
16 look into further?

17 **DR KAUFMANN:** I would do my sensitivity analyses, that's for
18 sure. I think I would look to some of the input prices as
19 well, the construction costs that we've talked about,
20 whether there are any sort of deflators we could use for
21 construction costs within New Zealand, maybe re-examine
22 the wage data as well, the wage data in New Zealand. I
23 think those are some of the biggest issues.

24 **MS BATES:** You said that New Zealand costs are 20 to 30
25 percent higher than US costs and that was on the basis of
26 which way you decide to calculate the exchange rate, and
27 as I apprehend your reasons, or the reasons for this, you
28 think their economies of scale, low customer density and
29 low volume density; are those some of the reasons you
30 think that the costs are higher?

31 **DR KAUFMANN:** Well, we didn't find that the costs were higher

1 in New Zealand, in fact what we found was that the costs
2 were lower, even if you come up with very simple --

3 **MS BATES:** Sorry, I've got that wrong, you say 20 to 30
4 percent lower?

5 **DR KAUFMANN:** That's right, lower than predicted, lower than
6 predicted. The factors that -- if you just kind of take a
7 naive, if I could use that word, comparison.

8 **MS BATES:** You can with me.

9 **DR KAUFMANN:** If you look at costs per customer for these two
10 companies relative to the US you'd find they're a little
11 bit lower, but those cost per customer measures don't
12 control for differences in economies of scale and
13 differences in customer density, for example, and once you
14 do control for those things you find that those factors
15 tend to disadvantage the companies. If you take proper
16 account of those factors then you would expect the
17 company's costs to be much higher than they actually are.
18 So what that shows is that the companies are actually
19 successful in keeping their costs below what you would
20 expect, given the conditions that they're operating under.

21 **MS BATES:** I see, I haven't understood you properly, so now I
22 do. What about the cost of capital, is there any --
23 because you said that was an important factor, didn't you,
24 in the costs?

25 **DR KAUFMANN:** Yes.

26 **MS BATES:** What about the cost of capital comparison between
27 US and New Zealand?

28 **DR KAUFMANN:** It was somewhat higher in the US but we did some
29 sensitivity analysis, so we varied that by plus or minus 1
30 percent and found it had almost no impact on the results.

31 **MR STEVENS:** I've just got one question really, it comes down

1 to your sample of the US firms. Are the US firms in your
2 sample more vertically integrated than the New Zealand
3 firms? The reason I ask it is how did you deal with the
4 assumptions on the allocation of joint cost when you're
5 working through your samples.

6 **DR KAUFMANN:** Some companies are stand-alone gas companies and
7 some are combination gas and electric companies, so for
8 the companies that are combination gas and electric we did
9 allocate administrative and general expenses and plant
10 based on the relative shares of other O&M costs between
11 electric and gas, for example. So let's say a company had
12 80 percent of its O&M costs in electric and 20 percent in
13 gas, which is about right for a lot of companies, then we
14 would take those A and G costs, administrative and general
15 costs, and we'd allocate them 80/20 between electricity
16 and gas.

17 **MR STEVENS:** Do you believe that introduces more of an
18 arbitrary judgment as opposed to Australia where it's less
19 vertically integrated?

20 **DR KAUFMANN:** Australia or New Zealand?

21 **MR STEVENS:** Australia compared to the New Zealand
22 comparisons. I guess what I'm trying to reflect is
23 whether your sample introduced any more variances that you
24 had to allow vis-a-vis comparisons with the Australian
25 sample.

26 **DR KAUFMANN:** I don't think so, because I know -- for one
27 thing a number of the Australian companies are vertically
28 integrated, they have electricity distribution and gas
29 distribution. Energex does, TXU, United Energy, they all
30 have electricity and gas and Envestra is a company that
31 has multi-jurisdiction gas companies and I believe there

1 could be some very severe cost allocation issues there in
2 terms of how those costs are allocated. So I think
3 they're different but I don't think that the cost
4 allocation issues are necessarily any more severe in the
5 US.

6 **MR STEVENS:** Thank you.

7 **CHAIR:** When you used the 20 percent did you use that for
8 Vector as well, the cost allocation?

9 **DR KAUFMANN:** No, we did experiment with different allocations
10 of common costs, but we found that that didn't make much
11 difference as well, so rather than complicate the results
12 and have a lot of different costs for the companies, we
13 just used the ACAM costs.

14 **CHAIR:** I'll just as Dr Lawrence please to ask questions.

15 **DR LAWRENCE:** Larry, we've been through some of these issues
16 before, but just briefly, you mentioned some of the
17 flexibility properties of the translog functional form
18 that you use in your cost function, I think you'd agree
19 that the multilateral TFP function that we use and also
20 the Fisher index that's used in the productivity growth
21 study are both what we call superlative functional forms,
22 in other words they're equivalent to flexible technology
23 so they have essentially the same property as the translog
24 cost function in terms of ability to approximate any
25 underlying cost structure.

26 **DR KAUFMANN:** Yeah, I certainly agree with that in a
27 theoretical sense, there's no doubt about that. I think,
28 though, as a practical matter and as a practitioner the
29 exact correspondence between what you would get out of a
30 translog function and what you might get out of a
31 multilateral index, in practice they often aren't the

1 same, and they're usually not.

2 **DR LAWRENCE:** The translog functional form that you use, it's
3 fairly dated functional form now in that most of the more
4 recent studies use things like generalised quadratic that
5 are able to approximate curvature conditions globally.
6 One of the problems that's often found with translog cost
7 functions is that they don't satisfy some of the key
8 curvature conditions, particularly concavity in prices. I
9 was just wondering if you've checked the concavity
10 conditions on your model and all the observation points.

11 **DR KAUFMANN:** Yeah, we have. Yeah, we always do that. I
12 don't think it was 100 percent satisfaction but it was
13 very high. I could check into that if you'd like.

14 **DR LAWRENCE:** It's important that it does satisfy those
15 conditions if it's going to provide an accurate
16 representation.

17 Moving on to the issue that I raised earlier regarding
18 the way you calculate your cost function and the
19 implications of that for the characteristics of your
20 sample, as I understand it you estimate your cost function
21 on pool data and you've actually made a change in this
22 study in that you've actually included the New Zealand
23 firms in that estimation process, is that correct?

24 **DR KAUFMANN:** It's panel data it's not pooled.

25 **DR LAWRENCE:** I mean pool time series cross-section, so panel
26 data in other words.

27 **DR KAUFMANN:** That's correct, yeah.

28 **DR LAWRENCE:** I think that has some important implications
29 given the fact that what you're looking at here are the
30 smallest and the third smallest distributors in your
31 sample based on your main output measure customer numbers

1 and you've got an extreme range in the size of the sample,
2 it's very skewed towards large distributors. You've got a
3 quarter than are 10 times bigger, actually even more,
4 probably 15 times bigger than the largest of the two
5 New Zealand distributors that you've included and you've
6 got one that's even 50 times larger.

7 When you use pooled data, panel data, in other words
8 you're pooling all the distributors into the one data set,
9 given the characteristics of regression techniques, the
10 large distributors are going to actually have what I would
11 argue is a disproportionate weight in the coefficients
12 that you estimate, because essentially given the quadratic
13 nature of progression techniques, the large observations
14 in the sample get a disproportionate amount of weight
15 relative to say using market shares costs, for instance,
16 which is probably a more conventional way of doing it.

17 You're probably aware that in the electricity work we
18 did we actually, for that reason, similar situation where
19 you had a large skewness in the sample with some large
20 distributors and some very small ones, we actually
21 estimated individual cost functions for each distributor
22 and that gives you probably a better representation for
23 the small distributors compared to your pooled approach of
24 including the very large distributors which then get most
25 of the weight effectively in forming the coefficient.
26 Have you thought about how to handle that?

27 **DR KAUFMANN:** Yeah, we had -- you're right, the large
28 companies get a bigger weight, that's certainly true. The
29 issue I think is whether that's disproportionate, as you
30 say. I think it's not unreasonable to expect to place
31 more weight on certain companies. We did have a very

1 thorough review of our econometric approach as part of the
2 Boston Gas Project and what came out of that review was
3 that the main concern we had with our estimation technique
4 was heteroskedasticity and that we weren't correcting for
5 that and that again is going to be related to the
6 influence that large companies have on the estimates.

7 Variance is going to be much higher, variance in the
8 error term would be much higher for the larger companies
9 relative to the smaller ones. We did correct that. I do
10 think that the heteroskedasticity corrected estimates do
11 lead to -- they do take care of a lot of the issue and the
12 impact that those companies might be having on the
13 estimates.

14 **DR LAWRENCE:** I'm not familiar with the exact characteristics
15 of Boston Gas, but I suspect it's considerably larger than
16 the New Zealand utilities, it wouldn't be either the
17 smallest or the third smallest utility in your sample for
18 instance.

19 **DR KAUFMANN:** No, it's not. That's why we added the companies
20 to the sample, we thought it was important to do that, and
21 you're right it's much more difficult to make good
22 inferences out there on the tails of the distribution like
23 that. But that is going to be reflected in the confidence
24 intervals and the T-statistics, they do tend to widen as
25 companies get further and further from the mean. So the
26 fact that we've got relatively wide confidence intervals
27 for these companies and they're still significant, in a
28 sense we're taking care of that issue through the
29 estimation technique.

30 **DR LAWRENCE:** You're partly addressing, I wouldn't say you're
31 necessarily taking care of it completely.

1 If I could move on to another point. I'm somewhat
2 surprised to see the very small number of operating
3 environment variables that you've included in the study.
4 We have in Vector's submission, for instance, that they
5 think some of the key things that should be accounted for
6 in doing international comparisons are things like colder
7 weather, greater population density, no mature gas
8 reticulation networks, access to abundant quantities of
9 gas and environmental considerations.

10 On Monday we had Mr James, the CEO of NGC, make the
11 observation that the US and New Zealand were very
12 different, particularly because of the influence of
13 climate in the US, much colder temperature, particularly
14 in northern US I guess, and what he called a culture of
15 consumption. I think what he meant by that was the
16 lifestyle characteristics.

17 I know when I lived in North America it was quite
18 unusual to see people in the winter having their houses
19 heated up to about 25 degrees walking around in t-shirts
20 inside when there's 4 foot of snow outside, it tends to be
21 very different lifestyle in the southern hemisphere where
22 you tend to heat your houses not near as much in the
23 winter and you actually wear a jumper inside in the
24 winter. So those sorts of things are going to have an
25 impact on the international comparisons that you make.

26 I don't see how those sorts of very important
27 considerations enter into your model when effectively the
28 only operating environment conditions you are including as
29 a measure is one measure of size and I think cast iron
30 pipes or something. While that might be similar for
31 important for fairly similar types of utilities, I think

1 in the overall scheme of things in regard to international
2 comparisons is probably a third order issue.

3 I appreciate there are statistical difficulties why
4 you mightn't include some of these things, but I think
5 you'd have to acknowledge they're very important in this
6 sort of study.

7 **DR KAUFMANN:** I do acknowledge that. I think a number of
8 these things are reflected, maybe not explicitly but
9 implicitly, like the wasteful sort of North American
10 culture. If that's in fact true then that would be
11 reflected in volumes and we've got volumes as an output in
12 the model.

13 **DR LAWRENCE:** The difficulty there is that doesn't distinguish
14 between the operating environment and, say, another
15 utility that's situated in the southern hemisphere that's
16 similar to NGC or Vector but just happens to be larger.
17 You're probably aware in previous studies that have been
18 done of gas distribution networks people quite often
19 include things like degree days as a measure of those sort
20 of extremes of climate which is probably pretty important
21 to include.

22 **DR KAUFMANN:** That's right, we tested heating degree days as a
23 variable that didn't -- it wasn't significant, so we did
24 try that.

25 **DR LAWRENCE:** That probably reflects my point, when you come
26 to do a lot of these things econometrically you're
27 actually running into a lot of multicollinearity problems,
28 and problems in terms of estimation, where particularly if
29 you don't have a large number of years I guess, where
30 these things are essentially entering almost like
31 constants, it's like a set of dummy variables almost. In

1 other words you're not getting a lot of variation in these
2 key operating environment variables from year to year,
3 which makes it hard to estimate an econometric cost
4 function that takes those things into account and come up
5 with significant results, even though those sorts of
6 influences are very important.

7 **DR KAUFMANN:** Well, another thing that we have tried, which is
8 correlated with heating degree days, and we tried to do
9 this in New Zealand as well, but the data weren't there,
10 was frost depth. Frost depth, that's obviously going to
11 be correlated with heating degree days, but it has a more
12 direct relationship to the gas distribution business which
13 is if you have a lot of frost then -- if you're operating
14 in an area where the frost depth is greater then that
15 tends to get into pipes and lead to leaks and things like
16 that. So it tends to raise costs at the same time that it
17 might tend to raise consumption, or be correlated with
18 factors that raise consumption.

19 So we have control for influences like that in some of
20 our other US work. I agree some of those things can be
21 important. The data weren't there to implement those
22 types of variables in the New Zealand context.

23 I guess as a general matter I do agree that, like I
24 said earlier, this is an imperfect science, we're never
25 going to get everything, we're never going to be able to
26 quantify every cost driver and get an independent estimate
27 of how much every potential cost driver is independently
28 affecting cost. So it is imperfect and I think that's one
29 of the things you have to keep in mind with any
30 benchmarking study. But having said that, I guess it's
31 really just a matter of magnitude of those imperfections

1 relative to what we've done because we are picking up 97
2 percent of the variation in costs here.

3 **DR LAWRENCE:** You're using some statistical measures to
4 reflect the characteristics of your cost function, but you
5 haven't really included the sort of information that we
6 would normally look at ourselves in doing econometric
7 studies, and that is, for instance, a plot of residuals I
8 think is usually your first line of examination of the
9 reasonableness of your model to try and identify outliers,
10 and it would be good if you included some of that sort of
11 information in your report.

12 But that leads me to the next point that I was going
13 to make, or question I was going to ask you, and that is
14 from a Regulator's perspective it's very important that
15 these sorts of studies be transparent and reproducible,
16 and you've put up the translog cost function earlier and
17 you make the statement in your report that that is a
18 general form of translog cost function. We don't actually
19 see the exact estimate equations that you've used.

20 You also made the comment that it took one of your
21 staff a couple of months or something to implement the
22 heteroskedasticity adjustment. I guess the thing that
23 concerns me about econometric studies in this sort of
24 context, particularly in terms of reproducibility, is even
25 if you've got the same data set that the analyst is using,
26 there are so many ways in which the results can be
27 tweaked, if I can use that term, or -- I mean quite apart
28 from that there are different econometricians will have
29 different ways of implementing their equations, they'll
30 use slightly different versions of the cost function,
31 they'll include variables in a slightly different way and

1 importantly they'll have different error structures and so
2 forth which is what you're talking about with
3 heteroskedasticity.

4 So although you make the statement in your report that
5 you think your approach gets away from being a black box,
6 so to speak, I think econometric approaches in general
7 still suffer significantly from that in that they are
8 fairly subjective in many ways, and I'd go a step further
9 and say, I think you'd have to agree, that any
10 econometrician worth their salt given sufficient time can
11 usually come up with a specification that's going to make
12 even a relatively poor performing utility look pretty good
13 depending on how you specify things. In that sense
14 econometric techniques, they're neither particularly
15 transparent nor reproducible.

16 I guess the second dimension relates to data. I
17 believe your database is a commercial product that's not
18 normally made generally available, so even if we have the
19 exact specification of the econometrics that you've
20 implemented it still makes it difficult to reproduce; just
21 wondering if you wanted to comment on those observations.

22 **DR KAUFMANN:** In terms of the econometrics I don't agree that
23 it's possible, even for the most gifted econometrician, to
24 make a really bad company look good. There's only so much
25 you can do. What we find, and I don't mean that in a
26 pejorative or any sort of -- I wasn't putting any spin on
27 that, if an econometrician was dedicated to making a bad
28 company look good they might be able to make them look
29 better but you're never going to be able to make them look
30 great.

31 There's an expression in the US, kind of a rural

1 expression which is that you can put lipstick on a pig and
2 it's still a pig, and unfortunately I think that's true
3 about some of these companies is that the underlying truth
4 is going to be invariant to the econometric specification
5 that you choose. You can affect things on the margin, but
6 if a company's bad enough then it's going to continue to
7 look bad.

8 We find as we do this over and over again for a
9 number of clients that the same companies tend to appear
10 over and over as the good performers and the same
11 companies appear as the bad performers. Even as we change
12 specification from application to application as we update
13 the database, we do see similarities in terms of who's
14 good and who's bad. So I wouldn't deny that if you're a
15 really dedicated, results-driven econometrician that you
16 have some ability to influence the results, but I don't
17 think it's absolute, I just don't think that's the case.

18 In terms of the database you're right, we have
19 developed that, we can make that available under very
20 strict confidentiality guidelines, we've done that in the
21 past, but we typically don't do that because, I'm sure you
22 understand, it's kind of a sensitive product and we don't
23 want to kind of just give that out.

24 **DR LAWRENCE:** We may come back to you on that, we certainly
25 won't make a call on that at this stage.

26 I just wanted to -- I want to make the contrast that
27 there is scope for delivering calculations of efficiency
28 using the econometric methods even from the same database.
29 Index number methods are more straight up and down in the
30 sense that it's more transparent what's been done and it's
31 more easy for a third party to come in, use that database,

1 use a general description of what's been done and
2 reproduce the results exactly. It typically won't be the
3 case with econometrics.

4 Speaking of the databases, though, I just wanted to
5 move on and ask you a couple of questions, because I note
6 we're running short on time, on your database. You
7 mentioned in the report that you assemble the database
8 from a wide range of sources, I think you made that point
9 in your presentation as well.

10 I guess my concern there is how confident are you that
11 you've been able to assemble these widely different say
12 consistently, and in particular have you gone back and
13 checked the data in your database, the US firms that is?

14 **DR KAUFMANN:** Yes, we typically have to contact the companies
15 directly to get the data and we do. All 40 companies, and
16 more, I mean there are more companies that we stay on a
17 consistent basis with in terms of actually collecting the
18 data so we're in constant contact with them and constantly
19 updating the database, so we do have a direct line of
20 communication with the companies, and if we see a series
21 that don't look right, and that's one of the reasons we
22 look to a couple of sources of data to the extent we can,
23 and in most cases there are two sources of data, that
24 helps to provide some context and some ability to judge
25 whether the data we're being provided are accurate or not
26 and we will follow-up with the companies to clear that up.

27 **DR LAWRENCE:** One thing that concerned me about the way you've
28 constructed capital, the way you describe it in the report
29 is that you make a comment that you weren't able to get
30 exactly the same approach given the US data you'd had
31 given the way the New Zealand data is constructed, namely

1 using straight line depreciation whereas most perpetual
2 inventory type capital measures like the one I believe you
3 use are constructed using declining balance. Given that
4 capital is a -- it's a pretty important input in this
5 industry, I was just wondering how confident you were that
6 your US approximation is consistent with the New Zealand
7 data.

8 **DR KAUFMANN:** I'm not sure what your concern is, because we do
9 have a capital cost treatment and a depreciation rate that
10 is based on a straight line depreciation and so we've
11 constructed that for the US to be a straight line
12 depreciation which is the same thing that they use in
13 New Zealand. The one thing we couldn't do and we'd never
14 be able to do, is the sort of inventory based approach
15 towards developing the initial capital stock, the ODV type
16 capital measure; so we haven't done that and we couldn't
17 do that, but we do base that on a series of capital
18 additions, again going back 20 years, book value additions
19 that we apply straight line depreciation to which I think
20 reduces the concerns with comparability.

21 **DR LAWRENCE:** You mentioned in your presentation about the
22 1983 starting point 20 years; we're actually hearing
23 yesterday from a number of the presenters that the
24 pipelines here have an estimated life of 65 years, so 20
25 years is a relatively short period compared to overall
26 length of the pipeline, which means you're going to have a
27 certain degree of inconsistency in the way, or non-
28 comparability in the way the two capital stocks are
29 constructed.

30 **DR KAUFMANN:** Obviously we'd like to go back 6,500 years,
31 that's not feasible. But what we do is we apply to the

1 benchmark year, the 1983; we don't just take that as --
2 that number in and of itself is not the starting point for
3 the analysis. What we do is we apply, you're probably
4 familiar with this -- a triangularised weighted average of
5 asset price indexes to that capital stock and that's a way
6 to deflate it and to reflect the pattern of additions and
7 a pattern of depreciation up to that point, up to that
8 benchmark year.

9 What we use is we use a 40 year life of asset --
10 40 year triangularised weighted average which then
11 reflects 40 years of asset price inflation that are
12 weighted in a different way to reflect, according to the
13 triangularisation formula which you can show is equivalent
14 to a straight line depreciation rate. That's kind of a
15 roundabout way of saying that I think we do reflect
16 implicitly in our methods not just the 20 years of
17 additions, but the 40 years of additions that are
18 reflected in the benchmark. We're treating those in a
19 consistent way with respect to depreciation.

20 **DR LAWRENCE:** Yeah, but as I understand it you, by necessity,
21 have to use some type of historic cost as your starting
22 point in constructing your asset value in 1983.

23 **DR KAUFMANN:** That's right.

24 **DR LAWRENCE:** Then you'd use a perpetual inventory method from
25 there on.

26 **DR KAUFMANN:** Right.

27 **DR LAWRENCE:** Whereas the New Zealand data is constructed in
28 quite a different way, in that it's like a current
29 valuation when the ODV is done. That's going to introduce
30 some degree of non-comparability, in fact I'd argue a
31 potentially significant degree of non-comparability

1 between the capital stock series for the US and
2 New Zealand.

3 **DR KAUFMANN:** It's definitely different and there is really no
4 way that we can control for that.

5 **DR LAWRENCE:** I have a number of other questions, Larry, but I
6 think I've covered the main ones, so given the time
7 constraints.

8 **CHAIR:** Ask him to have them responded to in cross-submission
9 rather than here if you want. Do you want to at least put
10 them on the table and ask Dr Kaufmann to come back on
11 them. We might suggest, Dr Kaufmann, that Dr Lawrence put
12 the questions to you but you respond to them in cross-
13 submission because we've got an issue with time, but we do
14 want to give you the opportunity to respond to any
15 questions that we might have.

16 **DR KAUFMANN:** That would be fine.

17 **DR LAWRENCE:** One of those is I think you've made the point in
18 regard to our study that we weren't able to construct a
19 system capacity variable and it would be desirable to do
20 that, it's obviously hard to do that given the available
21 data and I notice you've used the simple kilometres or
22 miles of line as the proxy for system capacity in your
23 study. It would obviously be desirable to have a system
24 capacity measure in there that took account not only of
25 length but also size of pipe and pressures and the like.
26 It would be interesting to get your thoughts on what
27 implications that approximation are for your estimates.

28 The second point was covered by the Chair earlier
29 related to using the Melbourne construction price as a
30 proxy for New Zealand costs. I was very surprised by your
31 finding that the results are fairly insensitive to that,

1 because being a capital intensive industry the price of
2 capital is going to enter into your -- the construction
3 price of capital is going to enter into your capital price
4 that you include in your cost function, it's going to have
5 a fairly major influence on that variable that you
6 actually use in the cost function.

7 So I would have thought that it was potentially
8 sensitive to the construction price that was used, and I
9 have a number of concerns as to how representative
10 Melbourne construction costs, how accurately they reflect
11 New Zealand construction costs, given differences in the
12 size of the Melbourne market, for instance, higher growth
13 rates that have been experienced in Australia and quite a
14 number of other factors. So perhaps it would be useful to
15 do some more sensitivity analysis if possible on the
16 influence of that variable. That's all my questions for
17 now.

18 **CHAIR:** I'll just see if there are further questions from
19 anyone else.

20 **MR SELL:** As with Dr Lawrence's questions and in the interests
21 of time I think I'd be happy if these were answered in
22 cross-submissions. My first question is really following
23 up on a question that Commissioner Stevens asked you about
24 making sure that the scope of the businesses that you're
25 comparing in the US is equivalent to the scope of the
26 businesses here in New Zealand. I think you answered the
27 question by talking about how some of the US businesses
28 were electricity and gas business, but I didn't hear a
29 very clear answer about the scope of the gas businesses.

30 I guess the point I'm getting at here is the fact that
31 these are distribution businesses and they don't really

1 have a retail activity, certainly not on the scale down to
2 the mass market of the retail activities of the US
3 businesses. I guess what I'm wondering is whether for the
4 US businesses you had cost data from which you were able
5 to easily isolate the distribution-only activities, or
6 whether you had to do some sort of allocation process.

7 **DR KAUFMANN:** That's right, I can answer that now, that
8 doesn't have to be a cross-submission; the cost definition
9 that we computed was in fact designed to be consistent
10 with the definition of distribution in New Zealand, so we
11 did take out the cost of retailing, we took out meter
12 reading, we took out customer information and service, we
13 took out billing and collection, all that kind of stuff.
14 We did have detail on that data for the US and all that is
15 taken out of the cost measure and the costs that we used
16 in the econometric study. So we are estimating the cost
17 drivers associated with distribution and not distribution
18 and retail.

19 **MR SELL:** Thanks for clarifying that.

20 Second question is on capital base that you used and
21 it's really a follow-on from the question Denis asked
22 earlier about the ODV valuations that are used here. I
23 must admit I'm still a little bit confused about how the
24 capital base has been determined in your study for the
25 New Zealand businesses vis-a-vis the US businesses. I
26 guess it's not clear to me. I understand that for the US
27 you've been able to build up the capital base using
28 historical data. For the New Zealand businesses I guess
29 I'm assuming that you didn't have access to the same level
30 of historical data and you probably had to use something
31 like the ODV valuations. If that were the case I don't

1 understand the significance of the capital cost indices
2 that you use, the Melbourne index that you used.

3 **DR KAUFMANN:** What that is, the ODV valuation that's a stock.
4 What we need to do is we need to develop a cost associated
5 with that stock and we needed to do that for both the US
6 and the New Zealand companies and since we're going to be
7 comparing the New Zealand companies to the US companies we
8 have to find a way to link the two. So that's where those
9 elements come in about the return on capital, depreciation
10 and the construction cost which is a way of deflating the
11 capital measure and since we need to link that -- the
12 price of construction to both, on a levels basis in the US
13 to New Zealand, that's where the Richardson construction
14 cost factors come in. We only had those for Melbourne,
15 and a couple of other cities in Australia I believe, but
16 nothing in New Zealand.

17 **MR SELL:** Okay, maybe in the interests of time we could just
18 as you if you're able to explain those adjustments a
19 little more in your cross-submission, because I guess the
20 major concern we would have is that we're comparing
21 perhaps historical cost asset bases from the US with what
22 are effectively replacement cost asset bases being used
23 here in New Zealand.

24 My third question is, I'm aware you've done studies in
25 the Australian context, and I would presume that those
26 were using the similar econometric model that you've
27 described to us today to compare Australian utilities with
28 US utilities and I guess we'd be interested in the results
29 of those, because potentially I guess it gives us an
30 opportunity to triangulate, if you like, and compare the
31 Australia versus New Zealand study that Dr Lawrence has

1 done. Any information that's in the public arena that
2 you're able to share with us on that would be helpful.
3 Again I'm sure in your cross-submission.

4 **DR KAUFMANN:** I'm certainly willing to do that, we do have a
5 number of things in the public domain. I know, and I'll
6 mention this in my response in the cross-submission, I
7 would definitely interpret those with some caution,
8 because as I discussed in the presentation we've made a
9 number of refinements in our method, in fact we're always
10 updating and upgrading methods, and the heteroskedasticity
11 adjustment was the biggest sort of update and I don't
12 believe any of our Australian work reflects that. So it
13 will be different in that sense and that's a very
14 significant difference. I'll talk about that in my
15 response.

16 **CHAIR:** We do need to break now, Dr Kaufmann, but I wanted to
17 ask you one question, and that is whether we use your
18 benchmarking work or we use the work done by Dr Lawrence,
19 or some variation of one or the other or both, you will be
20 aware that in the Draft Determination we talked about the
21 benchmarking study being indicative rather than definitive
22 information and in the end we didn't factor it in in any
23 way to quantitative analysis.

24 I guess the question we're left with is interesting as
25 these debates are, but a judgment to be made about the
26 weight to be put on information that comes out of one
27 benchmarking study or another. I'd like to hear your
28 thoughts on that matter because at the end of the day we
29 can debate everything here around the approach and
30 specification and the reliability and all sorts of other
31 issues, but then we must go away and decide what weight

1 will we put on the evidence that comes out of it.

2 So I wondered if you had any thoughts on that, and
3 I'll use my prerogative of the Chair and ask you to
4 respond now rather than in cross-submissions.

5 **DR KAUFMANN:** Thoughts on the weight in general that you
6 should place on benchmarking studies, is that your
7 question?

8 **CHAIR:** Yes, well in the context of this inquiry.

9 **DR KAUFMANN:** I don't want to punt on that question. I know
10 this is a complicated inquiry and I know you're
11 considering a lot of different issues and I'm really not
12 up to speed on the full debate, on the full set of issues
13 you're considering. So it is difficult for me to say how
14 much weight you should place on benchmarking as opposed to
15 the other evidence you're considering because I don't
16 really know what that other evidence is. I don't know,
17 does that satisfy you?

18 **CHAIR:** Not particularly no, but I accept that you may not be
19 aware, so perhaps we'll ask you to give a consideration
20 once you've had a chance to see and come back. I think
21 because of your experience in forums such as this the
22 Commission would value hearing your considered response to
23 it, and at the end of the day this discussion has been
24 very interesting, but the real issue is going to be how
25 much weight do we put on any bit of the evidence before us
26 and what would be the considerations that would lead us to
27 decide one way or the other about how much weight to put
28 on different bits of evidence.

29 You've presented a set of evidence and I think it
30 probably is appropriate to ask you, given the questions we
31 have to answer, how should that evidence be used and how

1 much confidence can we put on it in the context in which
2 we're trying to use it. So I'll ask you to look at the
3 context a little more widely and possibly come back to us
4 on that.

5 I do need to have a break now, particularly for the
6 transcriber. I would like to thank you, Dr Kaufmann, I
7 always find it a very significant benefit to the
8 Commission to have access to your expertise and advice, so
9 we are grateful to you once again and we've gone a bit
10 over time, so I hope that hasn't caused you any
11 difficulties.

12 We'll look forward to your cross-submission. I know
13 there's a number of issues we haven't had time to discuss
14 here but hopefully we'll get a comprehensive response from
15 you on the outstanding issues, so we'll thank you and also
16 Vector and NGC for sponsoring the work that you've done
17 for the inquiry. So with that we will break until 5 past
18 11, please, when we resume with Powerco. Thank you very
19 much.

20

21 **Adjournment from 10.50 to 11.05 am**
